

# Lecture 10 – Image segmentation III Regions

Prof. João Fernando Mari

<u>joaofmari.github.io</u>

joaof.mari@ufv.br

# Agenda

- Regions growing
- Region splitting and merging

## **REGIONS GROWING**

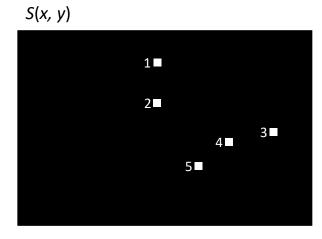

- f(x, y) is the input image;
- **S(x, y)** is an image containing seeds:
  - **S** is a binary image with the same size as image f.
  - Pixels with a value of 1 indicate the seeds and 0s indicate the other locations;
- **Q** denotes **some property** to be applied at each position **(x, y)**.

- f(x, y) is the input image;
- **S(x, y)** is an image containing seeds:
  - **S** is a binary image with the same size as image f.
  - Pixels with a value of 1 indicate the seeds and 0s indicate the other locations;
- **Q** denotes **some property** to be applied at each position **(x, y)**.

- Basic region growth algorithm (based on connectivity-8):
  - Reduce each connected component in S(x, y) to a single pixel (morphological erosion).
    - Label all pixels, r = [1, 2, 3, ... N].
  - For each seed r, generate an image  $f_r$  where:
    - $f_r(x, y) = r$ , if the input image pixel satisfies Q;
    - $f_r(x, y) = 0$ , otherwise.
  - The output image g is formed by appending to each seed in  $\bf S$  all the pixels labeled with the number  $\bf r$  in  $\bf f_r$  that are 8-connected to that seed.
    - In case of conflict, assign the lowest label. "The first one takes all".

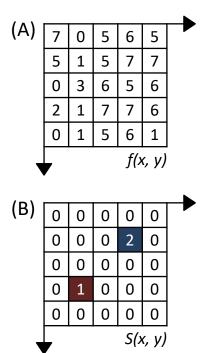

• (A) Original image f(x, y) with size 5 x 5, 3-bit depth (L = 8) and two seeds.

## **REGION SPLITTING AND MERGING**

#### Divisão e fusão de regiões

- Region splitting and merging algorithm.
  - 1. Divide into four quadrants any region R<sub>i</sub> in which Q(R<sub>i</sub>)=False.
  - 2. When it is not possible to divide a region, merge the adjacent regions  $R_j$  and  $R_k$  where  $Q(R_j \cup R_k) = Truth$ .
  - 3. Stop when merging is no longer possible.
